

Improvements in the wings and similar members of aircraft

Abstract

157,567. Page, F. H., and Page, Ltd., H. Oct. 24, 1919. Planes and the like, construction and arrangement of; steering, balancing, and regulating altitude.-To prevent " burbling " or eddying of the air above the leading edge of a plane set at a considerable angle of incidence, the plane is formed with a slot 1, or slots 1, 1<x>, extending transversely of the line of flight, and having the opening of each slot on the under surface of the wing in advance of the opening on the upper surface. The slot is formed by mounting in front of the main plane 5 an auxiliary plane 2, or auxiliary planes 2, 2x of wing section set at a considerably smaller angle of incidence than the main plane. The auxiliary plane 2 may be adapted to be moved into contact with the main plane 5 in order to close the slot, and for this purpose it may be carried on a number of arms 7 which are connected to the main plane and auxiliary plane by vertical pivots 8, 6 and can be swung transversely of the line of flight in the manner of a parallel ruler linkage by mechanism which can be operated by a hand lever near the aviator. The mechanism may operate simultaneously the auxiliary planes at the two sides of the machine and on the upper and lower planes of a biplane.

Classifications

- [B64C9/24](#) Adjustable control surfaces or members, e.g. rudders forming slots at the front of the wing by single flap
